MPLS for Cisco Networks builds up a full MPLS network, utilizing a core MPLS network and several customer sites. You will learn how to use OSPF, EIGRP, and RIP at the customer sites and redistribute them through the provider network. Learn how the routers swap labels, and how to control this, how to implement MultiProtocol BGP within the provider network, and how to set up VRFs (Virtual Routing

Multiprotocol Label Switching (MPLS), originating in IPv4, was initially proposed to improve forwarding speed. Its core technology can be extended to multiple network protocols, such as IPv6, Internet Packet Exchange (IPX), and Connectionless Network Protocol (CLNP). That is what the term multiprotocol means.

An MPLS network is commonly a backbone network comprised of MPLS-enabled routers called Label Switch Routers (LSR). Generally, the network consists of a core LSR with an edge LSR that applies labels to packets. This is the setup mechanism of an MPLS network: Routing tables of the different LSRs are computed with an Interior Gateway
