Deano Martin explains how he makes his own fungal compost to increase his soil fertility. Making a more fungal compost has been an aim of mine for some time. One of the ways that I do that is to not make 'hot' compost, keep the proportion of high carbon materials high, and to not turn unless it's needed.

Fertility-related soil properties can sometimes interfere with fungal growth in soil or in roots and alter mycorrhizal function, which in turn can limit its contribution to soil fertility. As earlier indicated, mycorrhizal fungi are diverse, and they can individually and collectively contribute to biological, chemical, and physical components of soil fertility in various ways.

Arbuscular mycorrhizal fungi can also benefit the physical characteristics of the soil, because their hyphae form a mesh to help stabilize soil aggregates. Arbuscular mycorrhizal fungi may also help to protect plants from root diseases present in the soil, and in some cases may help plants absorb copper and zinc from the soil.

Fungi are able to use nitrogen up from the soil, allowing them to decompose surface residue which is often low in nitrogen. Fungi are aerobic organisms. Soil which becomes anaerobic for significant periods generally loses its fungal component. Anaerobic conditions often occur in waterlogged soil and in compacted soils.

Soil biology is the study of microbial and faunal activity and ecology in soil. Soil life, soil biota, soil fauna, or edaphon is a collective term that encompasses all organisms that spend a significant portion of their life cycle within a soil profile, or at the soil-litter interface. These organisms include earthworms, nematodes, protozoa, fungi, bacteria, different arthropods, as well as ...

Fungi are abundant in soil, but bacteria are more abundant. Fungi are important in the soil as food sources for other, larger organisms, pathogens, beneficial symbiotic relationships with plants or other organisms and soil health. Fungi can be split into species based primarily on the size, shape and color of their reproductive spores, which are used to reproduce.

Climatic patterns can affect the types of fungal pathogens that are dominant in a region. For example, low fertility soils favour necrotrophic pathogens over biotrophic pathogens. Necrotrophic pathogens are distinguished from biotrophs because they kill host tissue prior to colonisation.

Instead, myriad populations of microbes, including both bacteria and fungi, perform important tasks that improve soil fertility. These fertilizing tasks are typically performed in the root zone of host plants, which make sugar available to fuel the process. Such tasks include nitrogen fixation.
